Molecular analysis for microbiologically influenced corrosion (MIC)

- Advances in molecular biological tools have allowed us to overcome the culture bias
- DNA is readily extracted from field samples to allow both qualitative and quantitative analysis of taxonomic and functional genes indicative of MIC related organisms in biofilms associated with surface corrosion
 - DGGE
 - qPCR

Molecular analysis for microbiologically influenced corrosion (MIC)

- Using these tools we can:
 - Detect MIC bacteria to provide timely corrective action
 - Quantify MIC bacteria to determine the appropriate aggressiveness of treatment
 - Monitor remedial efficacy in a corrosive environment

Using molecular biological tools to analyze biofilms

- A sampling bias remains in our analysis of biofilms
 - MIC biofilms are microbiologically diverse and structurally complex
 - Microbes active at the interface are most likely to initiate corrosion
 - Standard sampling of a biofilm on a corrosion coupon is a swab or whole coupon extraction
 - A sampling method that accounts for spatial heterogeneity of biofilms can improve the diagnosis of MIC

Using molecular biological tools to analyze biofilms

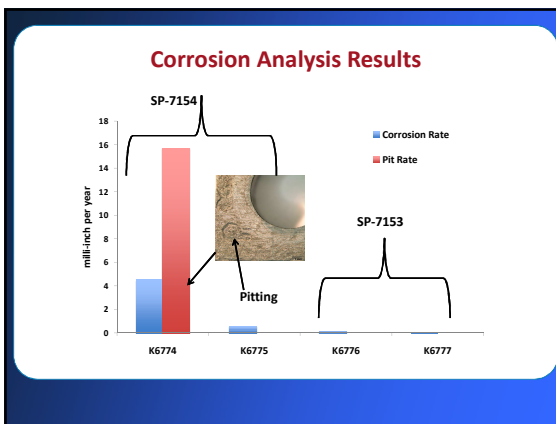

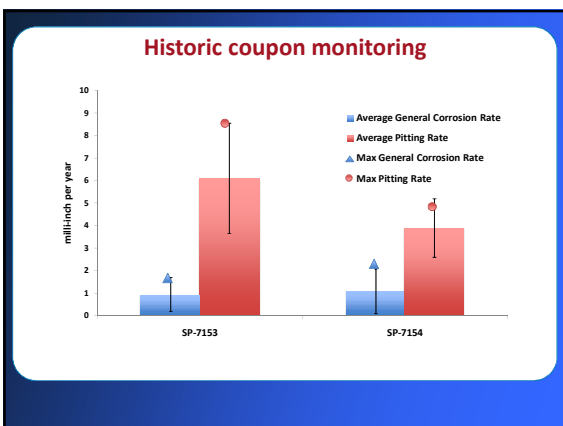

- To address this spatial bias in sampling of corrosion coupon biofilms we have developed a method to sample biofilms in layers
- A solution of aramid polymer in DMAc is applied to the surface in a thin layer. The coupon is then immersed in sterile distilled water. The aramid polymer then precipitates entrapping a layer of the biofilm matrix. The process is then repeated until all of the biofilm has been removed.

Experimental procedure

- Duplicate corrosion coupons installed in two natural gas well line “drips” for 100 days
- Surface deposits collected from one set with sterile swabs
- Aramid polymer layers were used to collect discrete layers of biofilm from the other set
- Coupons were examined for corrosion
- DNA was extracted from swabs and biofilm layers for microbial analysis

- Genera identified in K6776 polymer layers**
- K6776-1
 - *Staphylococcus* (promotes adhesion to metallic surfaces)
 - *Cloacibacterium*
 - *Variovorax* (implicated in corrosion of copper pipes)
 - *Nitrospira* (isolated from corroded iron pipe)
 - K6776-2
 - *Delftia* (implicated in corrosion of Ni-Cu and Ni-Zn coatings)
 - K6776-3
 - *Massilia* (highly adhesive to metallic pipe, detected in corroded lead pipe)
 - *Propionivibrio*, *Alcaligenes*
 - K6776-4
 - *Staphylococcus*, *Euzebya*, *Phenylobacterium*

- Conclusions**
- Discrete layers of biofilm collected using aramid polymer
 - DNA extracted from small aramid polymer samples
 - qPCR indicated the microbial community varied between aramid polymer layers, especially K6776.
 - Sequence analysis provided insight into microorganisms that may play a role in MIC

**In a 2nd case study in a sea water injection system
from a corrosion coupon with high rates of pitting
corrosion**

- Aerobes, facultative anaerobes
 - Facultative anaerobes, anaerobic hydrocarbon degraders, iron II and iron III reducers
 - Facultative anaerobes, anaerobic hydrocarbon degraders, iron II and iron III reducers
 - Strict anaerobes, SRB, iron reducers (including SRB known to directly uptake electrons from metallic iron)
- ↓
- Outside of biofilm
- Interior of biofilm
